electronic devices over the **world wide web**. A **web service** is a software function provided at a network address over the web or the cloud, it is a service that is "always on" as in the concept of **utility computing**.

The **W3C** defines a "Web service" as "a software system designed to support **interoperable** machine-to-machine interaction over a **network**". It has an interface described in a machine-processable format (specifically **Web Services Description Language**, known by the acronym **WSDL**). Other systems interact with the Web service in a manner prescribed by its description using **SOAP** messages, typically conveyed using **HTTP** with an **XML serialization** in conjunction with other Web-related standards."^[1]

The **W3C** also states, "We can identify two major classes of Web services, **REST-compliant Web services**, in which the primary purpose of the service is to manipulate **XML** representations of Web resources using a uniform set of "**stateless**" operations; and arbitrary Web services, in which the service may expose an arbitrary set of operations."^[2]
